## Blatt 6

### Exercise 6.1:

- (a) Specify a STRIPS planner for blocksworld transformations. Define operators  $\text{stack}(B1, B2)$  and  $\text{unstack}(B1, B2)$ , where  $B1$  and  $B2$  are blocks, and operators  $\text{pickup}(B)$  and  $\text{putdown}(B)$  where a block  $B$  is moved from or to the table. Use the primitive predicates  $\text{holding}(B)$ ,  $\text{on}(B1, B2)$ ,  $\text{ontable}(B)$  and the derived predicates  $\text{clear}(B)$ ,  $\text{armempty}$ .
- (b) Simulate plan generation for the blocksworld transformation shown in the figure below using backward planning and a goal stack. Initially, the stack contains the goal situation and its conjuncts as partial goals, e.g.

$\text{on}(a, b)$   
 $\text{on}(b, c)$   
 $\text{on}(a, b), \text{on}(b, c)$

The goals of the stack are processed as follows: If the top goal of the stack is fulfilled in the start situation, it is deleted, else it is replaced by an action which achieves this goal, and the delete list of that action is placed on the stack as new goals (including partial goals).

- (c) Is the planning procedure sound and complete for the blocksworld? In general?

### Exercise 6.2

Suppose that you have a STRIPS representation for actions  $a1$  and  $a2$ , and you want to define the STRIPS representation for the composite action  $a1-a2$ , which means that you do  $a1$  then do  $a2$ .

- What is the add list for this composite action?
- What is the delete list?
- What are the preconditions for the composite action?
- Using the delivery robot domain, give STRIPS representation for the composite action  $\text{move}(Ag, Pos1, Pos2)\text{-pickup}(Ag, Obj)$
- Give the STRIPS representation for the composite action  $\text{move}(Ag, Pos1, Pos2)\text{-move}(Ag, Pos2, Pos1)$
- Give the STRIPS representation for for the composite action  $\text{move}(Ag, Pos1, Pos2)\text{-pickup}(Ag, Obj)\text{-move}(Ag, Pos2, Pos1)$
- Use the idea of composite actions to detect cycles in STRIPS.
